5. Hi, Hydrogen!

0 points

Welcome to the QHack 2023 daily challenges! Every day for the next four days, you will receive two new challenges to complete. These challenges are worth no points — they are specifically designed to get your brain active and into the right mindset for the competition. You will also learn about various aspects of PennyLane that are essential to quantum computing, quantum machine learning, and quantum chemistry. Have fun!

Tutorial #5 — Hi, Hydrogen!

The Coding Challenge Competition is now closed, but you are welcome to continue working on the challenges until QHack ends on Feb 28 @5pm ET.

you will calculate the energy of the hydrogen molecule for various molecular charges and bond length combinations.

Challenge code

In the code below, you are given a few functions:

- `hydrogen_hamiltonian`: This function will return the qubit Hamiltonian of the hydrogen molecule, H_2, given the `coordinates` of both hydrogen atoms and the net molecular `charge`. You'll usually find H_2 with a charge of 0, but here we'll spice it up with a non-zero charge!
- `num_electrons`: In subsequent functions, we'll need the total number of electrons in the hydrogen molecule we're looking at. With a charge of 0, H_2 usually has just 2 electrons, one per hydrogen atom. Given the `charge`, how many electrons should H_2 have? ***You must complete this function.***
- `hf`: The "HF" stands for Hartree–Fock. This function's purpose is calculate the HF approximation — treat every electron as independent, electrons move under a Coulomb potential from the positively charged nuclei, and there's a mean field from the other electrons — for the ground state of the hydrogen molecule we're interested in. We'll use this later, so ***you must complete this function.***
- `run_VQE`: This function takes the `coordinates`, `charge`, generates the HF state, defines a `cost` function and minimizes it. ***You must complete this function*** by:
  - defining the gates within the `cost` function, using the `qml.AllSinglesDoubles` template with `singles` and `doubles` arguments defined below; and
  - returning what we want to minimize, namely the expectation value of the hydrogen Hamiltonian!

Here are some helpful resources:

- Building molecular Hamiltonians

The Coding Challenge Competition is now closed, but you are welcome to continue working on the challenges until QHack ends on Feb 28 @5pm ET.

- Quantum Chemistry documentation

Input

As input to this problem, you are given:

- `coordinates` (`list(float)`): the x, y, and z coordinates of each hydrogen atom
- `charge` (`int`): the charge of the hydrogen molecule. It could be positive, negative, or zero!

Output

This code must output the ground state `energy` (`float`) of the hydrogen molecule in question.

If your solution matches the correct one within the given tolerance specified in `check` (in this case it's a `1e-3` relative error tolerance), the output will be `"Correct!"` Otherwise, you will receive a `"Wrong answer"` prompt.

Good luck!

Code

Help

```
1  import json
2  import pennylane as qml
3  import pennylane.numpy as np
```

The Coding Challenge Competition is now closed, but you are welcome to continue working on the challenges until QHack ends on Feb 28 @5pm ET.

```python
def hydrogen_hamiltonian(coordinates, charge):
    """Calculates the qubit Hamiltonian of the hydrogen molecule.

    Args:
        coordinates (list(float)): Cartesian coordinates of each hydroge
        charge (int): The electric charge given to the hydrogen molecule

    Returns:
        (qml.Hamiltonian): A PennyLane Hamiltonian.
    """
    return qml.qchem.molecular_hamiltonian(
        ["H", "H"], coordinates, charge, basis="STO-3G"
    )[0]

def num_electrons(charge):
    """The total number of electrons in the hydrogen molecule.

    Args:
        charge (int): The electric charge given to the hydrogen molecule

    Returns:
        (int): The number of electrons.
    """

    # Put your solution here #
    return

def hf(electrons, num_qubits):
    """Calculates the Hartree-Fock state of the hydrogen molecule.

    Args:
        electrons (int): The number of electrons in the hydrogen molecul
        num_qubits (int): The number of qubits needed to represent the hy

    Returns:
        (numpy.tensor): The HF state.
    """

    # Put your solution here #
```

The Coding Challenge Competition is now closed, but you are welcome to continue working on the challenges until QHack ends on Feb 28 @5pm ET.

```python
def run_VQE(coordinates, charge):
    """Performs a VQE routine for the given hydrogen molecule.

    Args:
        coordinates (list(float)): Cartesian coordinates of each hydroge
        charge (int): The electric charge given to the hydrogen molecule

    Returns:
        (float): The expectation value of the hydrogen Hamiltonian.
    """

    hamiltonian = hydrogen_hamiltonian(np.array(coordinates), charge)

    electrons = num_electrons(charge)
    num_qubits = len(hamiltonian.wires)

    hf_state = hf(electrons, num_qubits)
    # singles and doubles are used to make the AllSinglesDoubles templat
    singles, doubles = qml.qchem.excitations(electrons, num_qubits)

    dev = qml.device("default.qubit", wires=num_qubits)

    @qml.qnode(dev)
    def cost(weights):
        """A circuit with tunable parameters/weights that measures the e

        Args:
            weights (numpy.array): An array of tunable parameters.

        Returns:
            (float): The expectation value of the hydrogen Hamiltonian.
        """

        # Put your solution here #
        return

```
