## Ising Uprising

500 points

Backstory

Zenda and Reece model Sqynet as a spin chain, and they come up with a strategy. What if, in addition to using plasma bombs and missiles to increase the temperature of the device, they use a strong magnetic field? After all, magnetic fields might pass through Sqynet's outer shell more easily. The

The Coding Challenge Competition is now closed, but you are welcome to continue working on the challenges until QHack ends on Feb 28 @5pm ET.   ✕

Ground state of an Ising spin chain

A simple way to model Sqynet is by considering it as a closed spin chain of length N. A spin chain contains particles of spin $1/2$ in each of its N sites. The spins may be pointing in the positive or negative z direction, and we consider that there may be an external magnetic field acting on the system.
Closed spin chain with $N \approx 10$ sites

Such a quantum system is described by the *Transverse Ising Hamiltonian*. For closed spin chain with a transverse magnetic field of intensity h, the Transverse Ising Hamiltonian reads

$$H = -\sum_{i=1}^{N} Z_i \otimes Z_{i+1} - h \sum_{i}^{N} X_i.$$

The subindices i indicate the spin site where the operators act. In a closed spin chain, we identify site $N+1$ with the first site.

A possible plan for Zenda and Reece is to use a strong magnetic field that changes the ground energy of Sqynet, causing it to malfunction.

Your task is to help Zenda and Reece calculate the effect of external magnetic forces on the ground energy. Using the Variational Quantum Eigensolver (VQE)

▶ **Epilogue**

Challenge code

In this challenge you will be given the following functions:

- `create_Hamiltonian` : In which you build the Transverse Ising Hamiltonian for $N = 4$ and a magnetic field intensity `h`. **You must complete this function.**

- `model` : This QNode builds a general enough ansatz for the ground state. This circuit must depend on some parameters `params`, which you will later optimize. It returns the expectation value of the Hamiltonian for the output state of the circuit. **You must complete this function.**

- `train` : This function returns the parameters that minimize the output of `model`. **You must complete this function.**

Input

As input to this problem, you are given:

- `h` (`float`): Magnetic field intensity applied to the spin chain.

Output

This code will output a `float` corresponding to the energy of the ground state.

If your solution matches the correct one within the given tolerance specified in `check` (in this case it's an relative tolerance of `0.1`), the output will be `"Correct!"` Otherwise, you will receive a `"Wrong answer"` prompt.

Good luck!

Code   ❓ Help

```
1  import json
2  import pennylane as qml
3  import pennylane.numpy as np
```
